

RICH GEMC SIMULATIONS

Contalbrigo Marco & Luciano Pappalardo
& Luca Barion
INFN Ferrara

Rich Meeting, 22 February 2012

Standard set-up

Geometry:

`rich_build_radtrap_mirror35_default.pl`

On the Jlab GEMC database

Validation:

- ✓ handle of MA-PMT copies
- ✓ volume overlaps
- ✓ refine materials
(to match aerogel transmission)
- user friendly layout

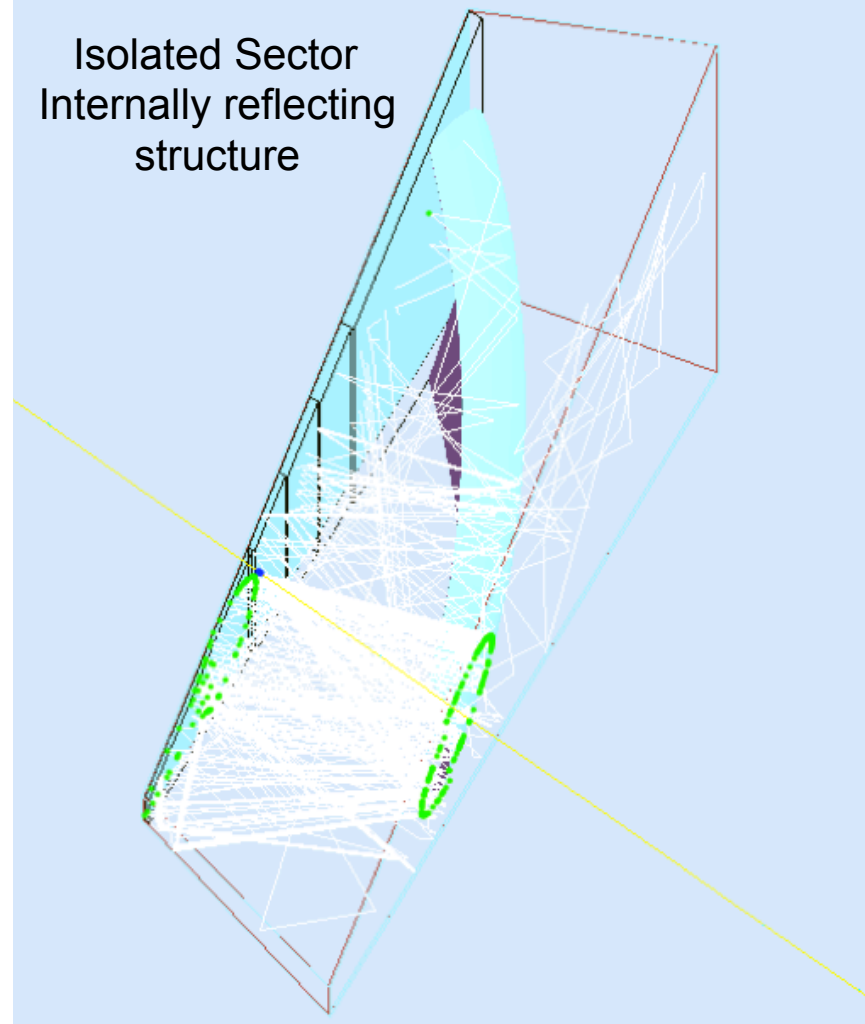

The Open or Isolated Sector

Open Sector
Pre Mirror Only

Isolated Sector
Internally reflecting
structure

Standard set-up

Material:

Mmaterials.cc

MDetectorConstruction.cc

On the Jlab GEMC database

Validation:

- ✓ MA-PMT window
- ✓ aerogel transmission (BELLE/Novosibirsk values)
- ✓ Rayleigh scattering
- Mirror imperfections/diffusion ?
- Lucite wrap ?

Standard set-up

Digitalization:

RICH_hitprocess.cc
RICH.bank
user_hits_def.txt

Number of anode pixels: 64 (8x8 matrix)
Pixel size / Pitch at center: 5.8 x 5.8 / 6.08 mm
Effective area: 49 x 49 mm
Dimensional Outline: 52 x 52 x 28 mm
Packing density (Effective Area / Esternal Size) : 89 %

On the Jlab GEMC database

Validation:

- ✓ match geometry
- ✓ QE energy range
- ✓ add to output
- ✓ QE curve ?

Standard set-up

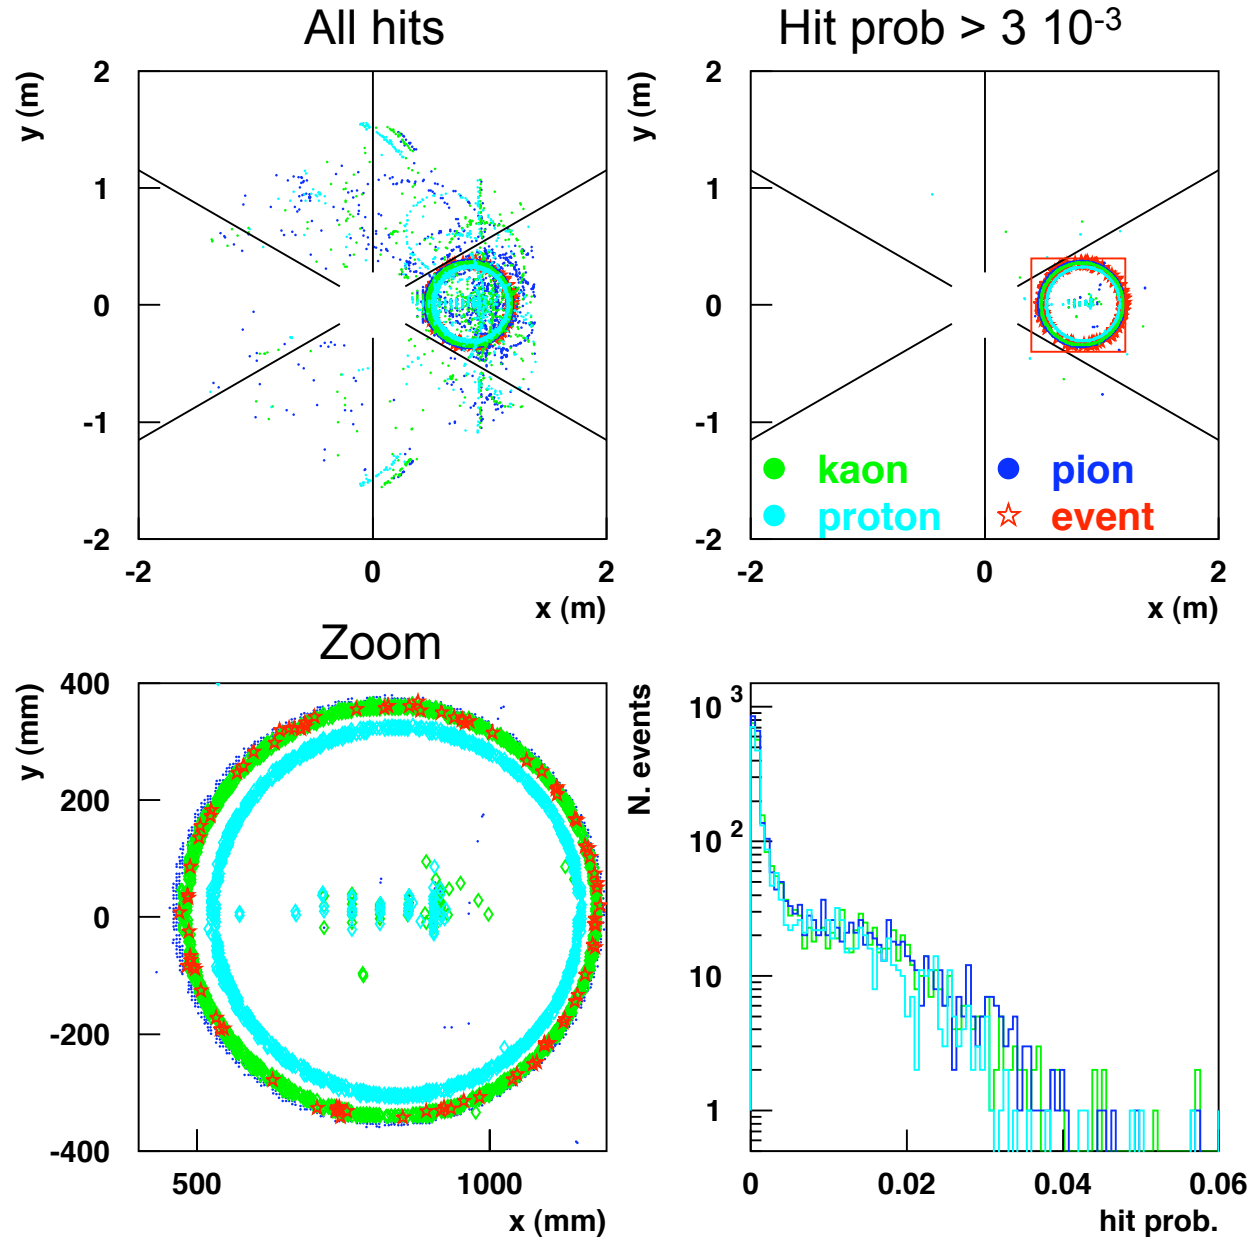

Reconstruction:

Private codes

Likelihood based on direct ray tracing

Validation:

- benchmark events
- x-check
- Cherenkov light from MA-PMT window
- Resolution on charged track impact parameters
- Performances and limits
- Background (Rayleigh)

Average N p.e.: NBA ?

Aerogel:

- $n=1.06$, $\lambda=5.5$ cm
- thick. increasing with radius:
2-4-6-8-10 cm
- Mirror: $14^\circ - 25^\circ$
- MA-PMTs: various
eff=0.65

Challenging with normal bi-alkali
N_{pe} a bit higher with standard set-up

Average N p.e.: NBA ?

Aerogel:

- $n=1.05$, $\lambda=5.5$ cm
- thick. increasing with radius:
2-4-6-8-10 cm

Mirror: $14^\circ - 35^\circ$

- 90% reflectivity

MA-PMTs: H8500
eff=0.65

Increase of direct photons due to MA-PMT window ?
Differences to be investigated

Average N p.e.: NBA ?

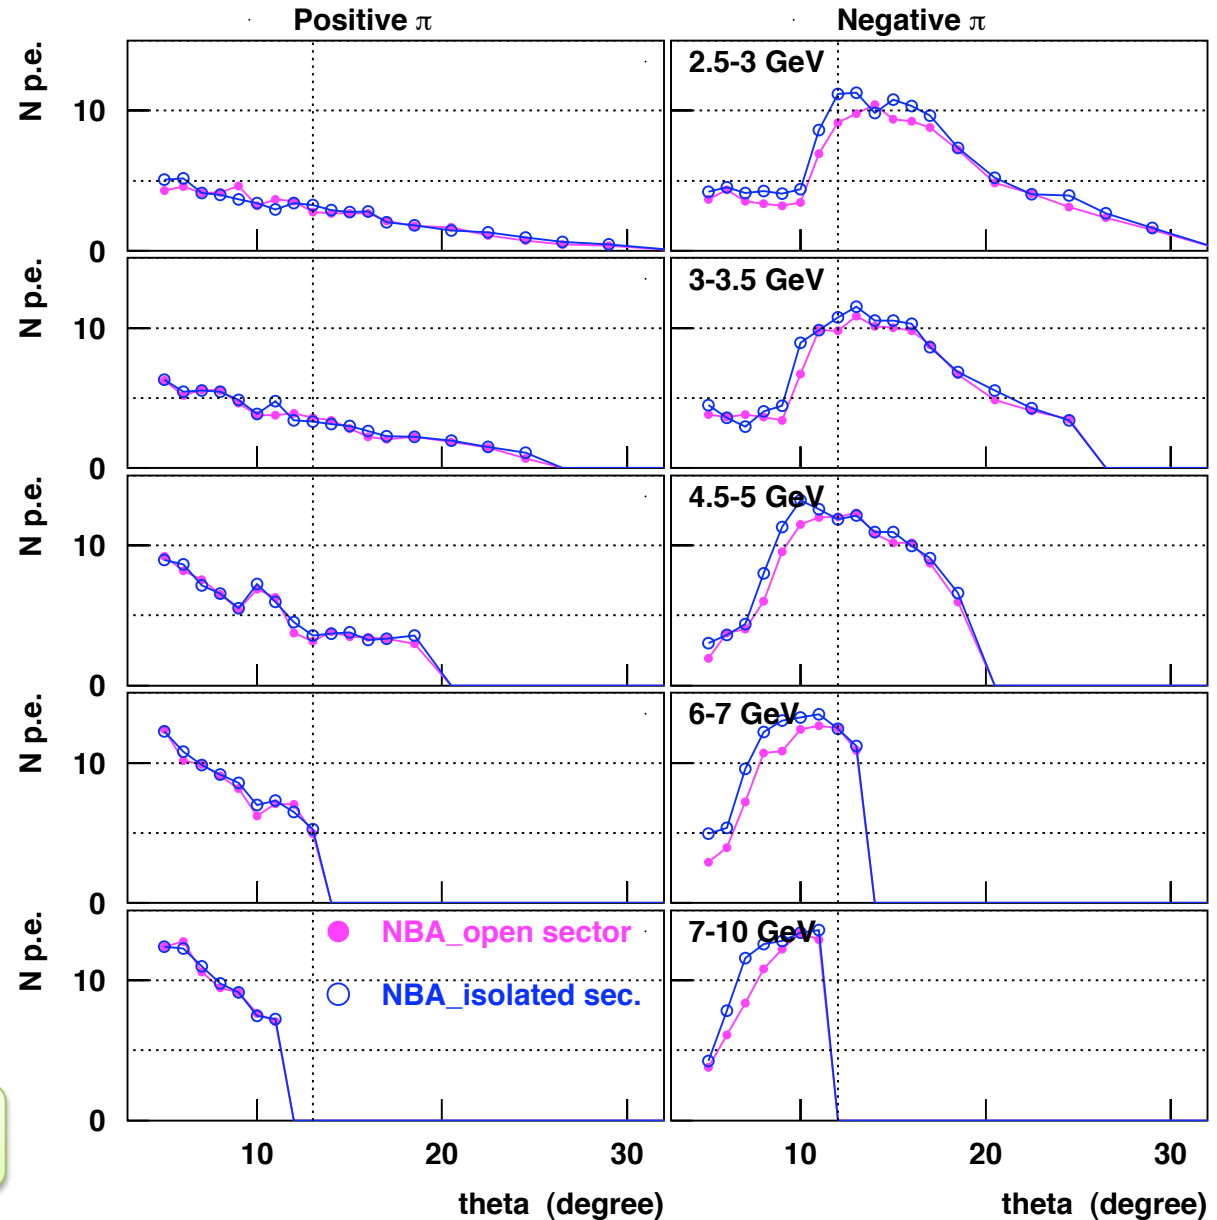

Aerogel:

- $n=1.05$, $\lambda=5.5$ cm
- thick. increasing with radius:
2-4-6-8-10 cm

Mirror: $14^\circ - 35^\circ$

- 90% reflectivity

MA-PMTs: H8500
eff=0.65

Minor difference on the number,
Major on the hit pattern

The likelihood

For a given track \mathbf{t} and particle hypothesis \mathbf{h} ($= \pi, K, p$) use **direct ray tracing** for a large number of generated photons to determine the **hit probability for each PMT**

The **measured hit pattern** is compared to the hit **probability densities** for the different hypotheses through a likelihood function:

$$L^{(h,t)} = \sum_i \log [P_{PMT}^{(h,t)}(i) C_{PMT}(i) + \bar{P}_{PMT}^{(h,t)}(i) (1 - C_{PMT}(i))]$$

(the hypothesis that maximizes $\mathbf{L}^{(h,t)}$ is assumed to be true)

$C_{PMT}(i)$ is the hit pattern from data $\begin{cases} = 1 & \text{if the } i\text{th PMT is hit} \\ = 0 & \text{if the } i\text{th PMT is not hit} \end{cases}$

$P_{PMT}^{(h,t)}(i)$ is the probability of a hit given the kinematics of track \mathbf{t} and hypothesis \mathbf{h}

$$P_{PMT}^{(h,t)}(i) = 1 - \exp\left(-\frac{N^{(h,t)}(i)}{\sum_i N^{(h,t)}(i)} n^{(h,t)} - B(i)\right)$$

$\bar{P}_{PMT}^{(h,t)}(i) = 1 - P_{PMT}^{(h,t)}(i)$ is the probability of no hit

$n^{(h,t)}$ is the total number of expected PMT hits

$B(i)$ is a background term (assumed to be 10^{-4} , fine with prelim. studies)

The pattern recognition

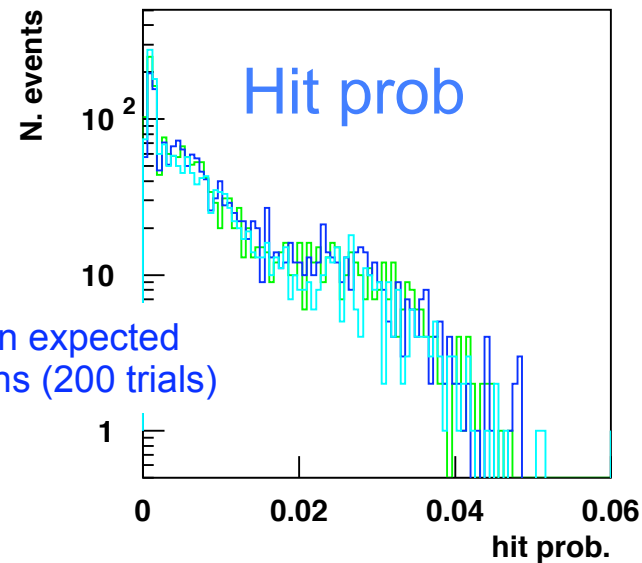

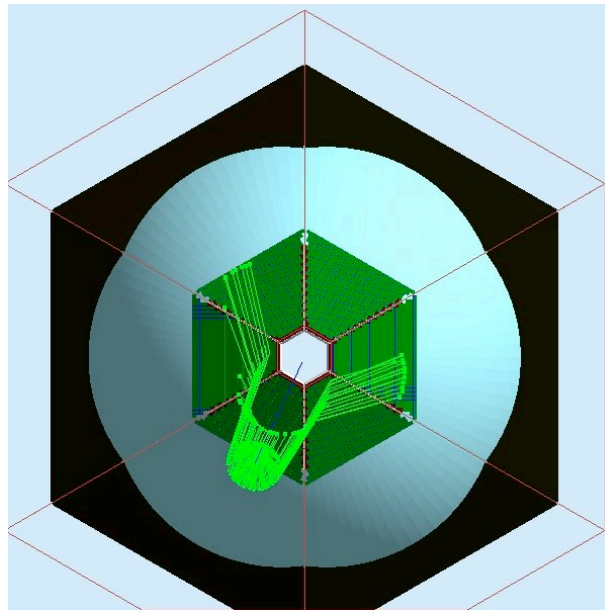

200 trials per point

Aerogel:

- $n=1.06$
- thick. increasing with radius:
2-4-6-8-10 cm

Mirror: $14^\circ - 25^\circ$

MA-PMTs: UBA

The goodness parameter

For a given track t and particle hypothesis h ($= \pi, K, p$) use **direct ray tracing** for a large number of generated photons to determine the **hit probability for each PMT**

The **measured hit pattern** is compared to the hit **probability densities** for the different hypotheses through a likelihood function:

$$L^{(h,t)} = \sum_i \log [P_{PMT}^{(h,t)}(i) C_{PMT}(i) + \bar{P}_{PMT}^{(h,t)}(i) (1 - C_{PMT}(i))]$$

Sum on all PMTs: it depends on the total number of readout channels and the background level

$$LH = L^{(h,t)} - L_{MIN}^{(h,t)}$$

L minimum: no signal, hits where only background is expected

$$R_{QP} = 1 - \frac{LH^{2st}}{LH^{1st}}$$

Quality parameter:

0 ambiguity \longrightarrow 1 good ID

LH performances for outbending particles

Aerogel:

- $n=1.05$, $\lambda=5.5$ cm
- thick. increasing with radius:
2-4-6-8-10 cm

Mirror: $14^\circ - 35^\circ$

- 90% reflectivity

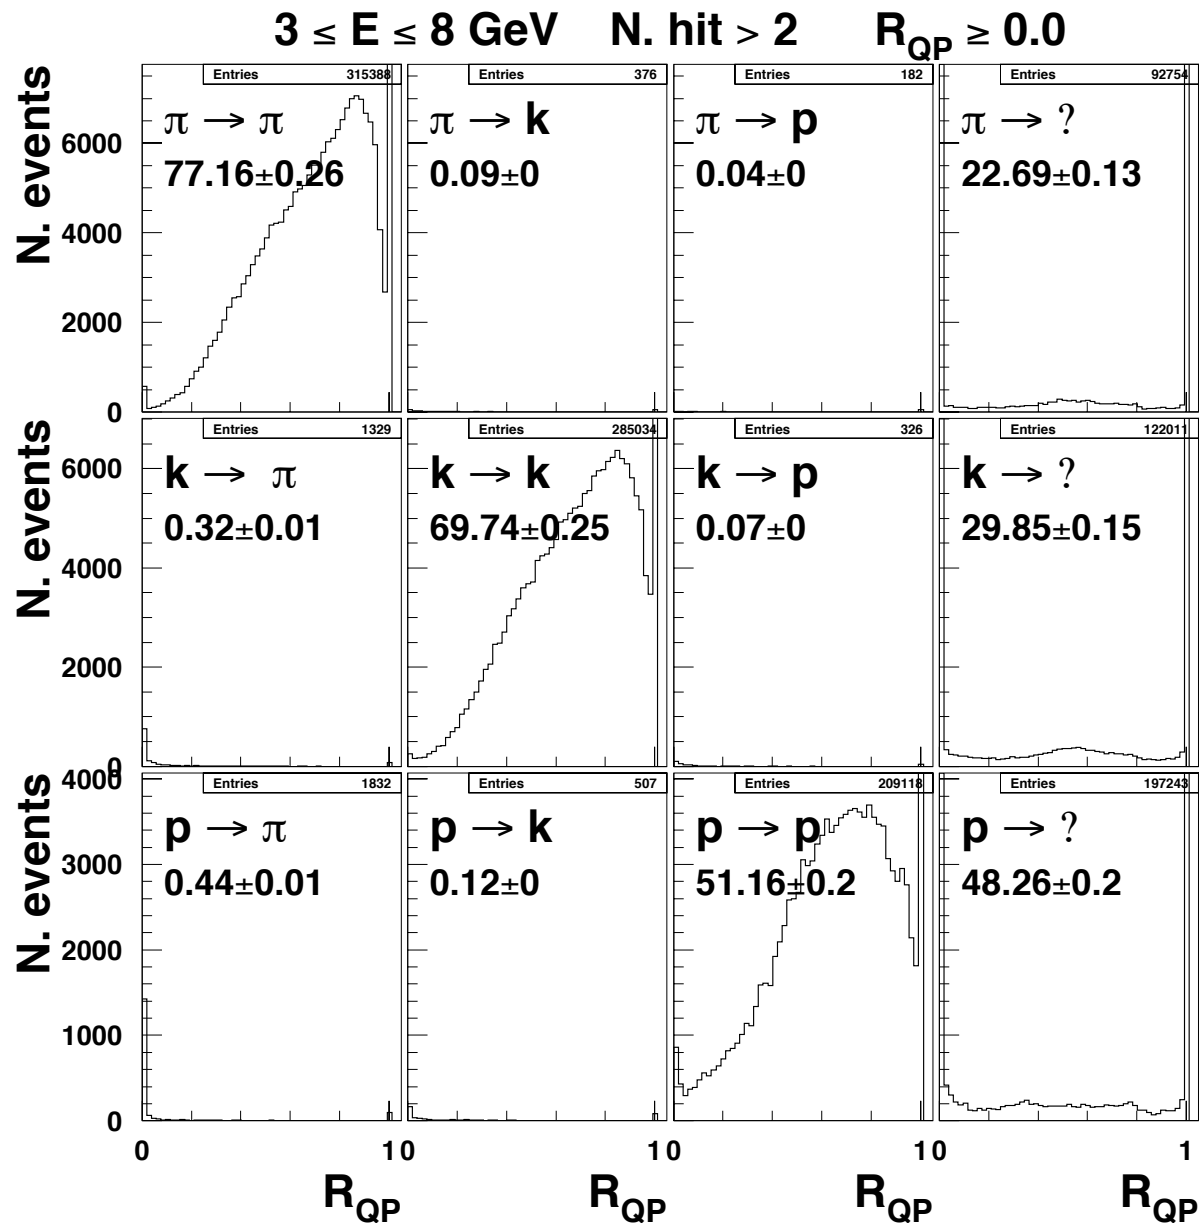

MA-PMTs: H8500

eff=0.65

Contamination \sim few per mill

Efficiency \sim 70 % for kaons

Identification quality:
in average good

LH performances vs momentum

Low momentum: smaller efficiency due to angular spread and small $N_{q.e.}$

High momentum: high uniform efficiency, ID more challenging (broader R_{QP})

$2.5 \leq E \leq 4 \text{ GeV}$ N. hit > 2 $R_{QP} \geq 0.0$

$6 \leq E \leq 8 \text{ GeV}$ N. hit > 2 $R_{QP} \geq 0.0$

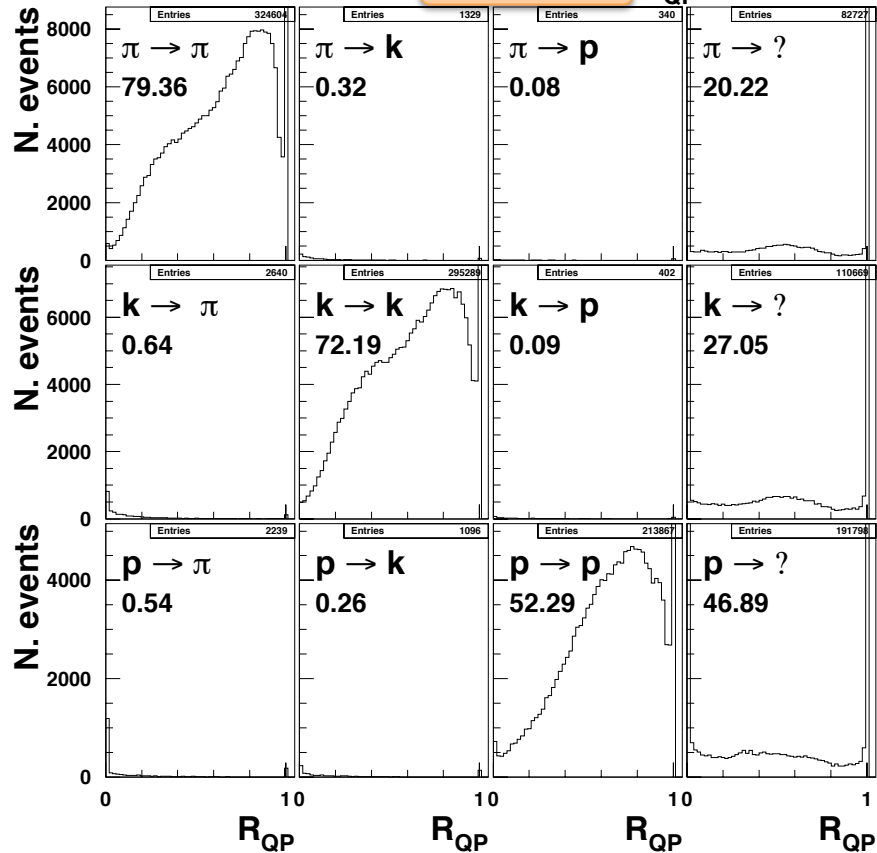

LH performances vs N. hits

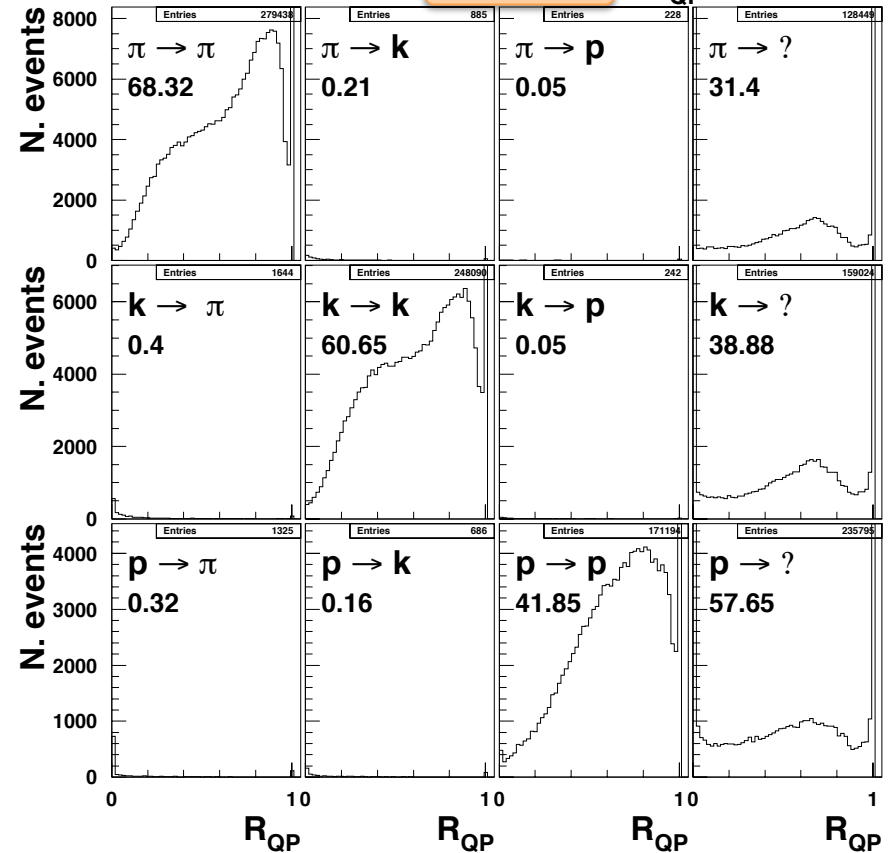

Up to 2 hits the RICH response is almost random

With 3 hits the identification start to be validated by R_{QP} goodness parameter

$3 \leq E \leq 8$ GeV **N. hit > 2** $R_{QP} \geq 0.0$

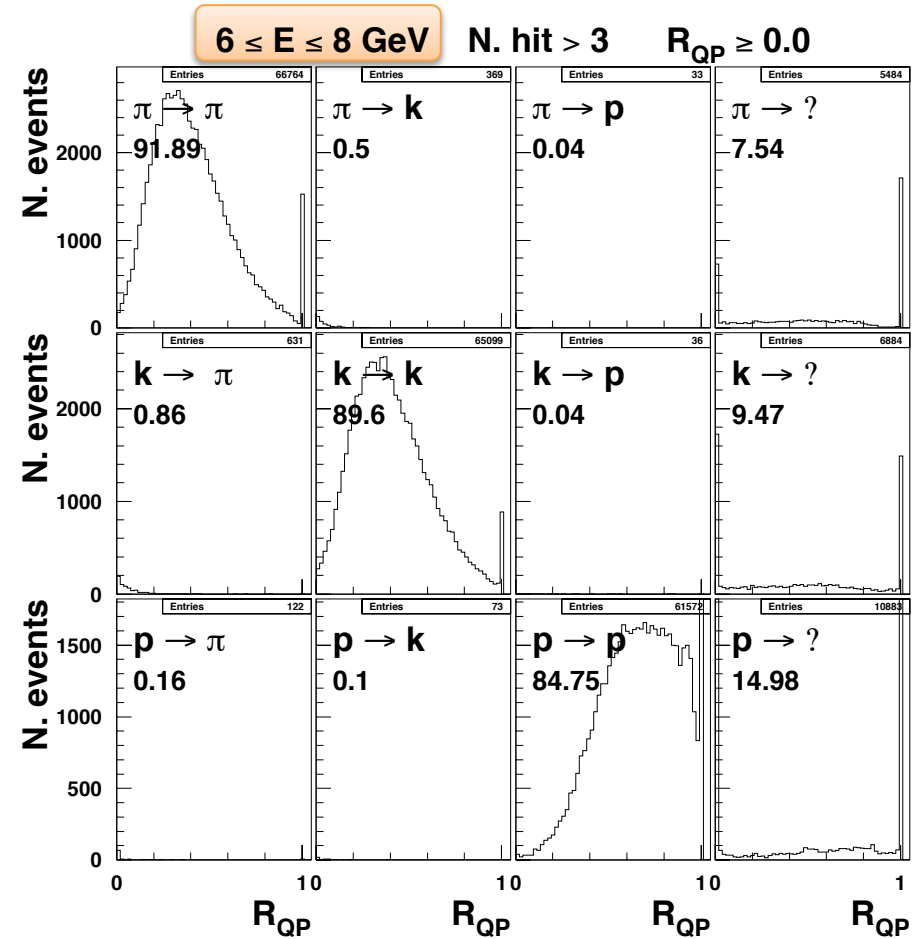

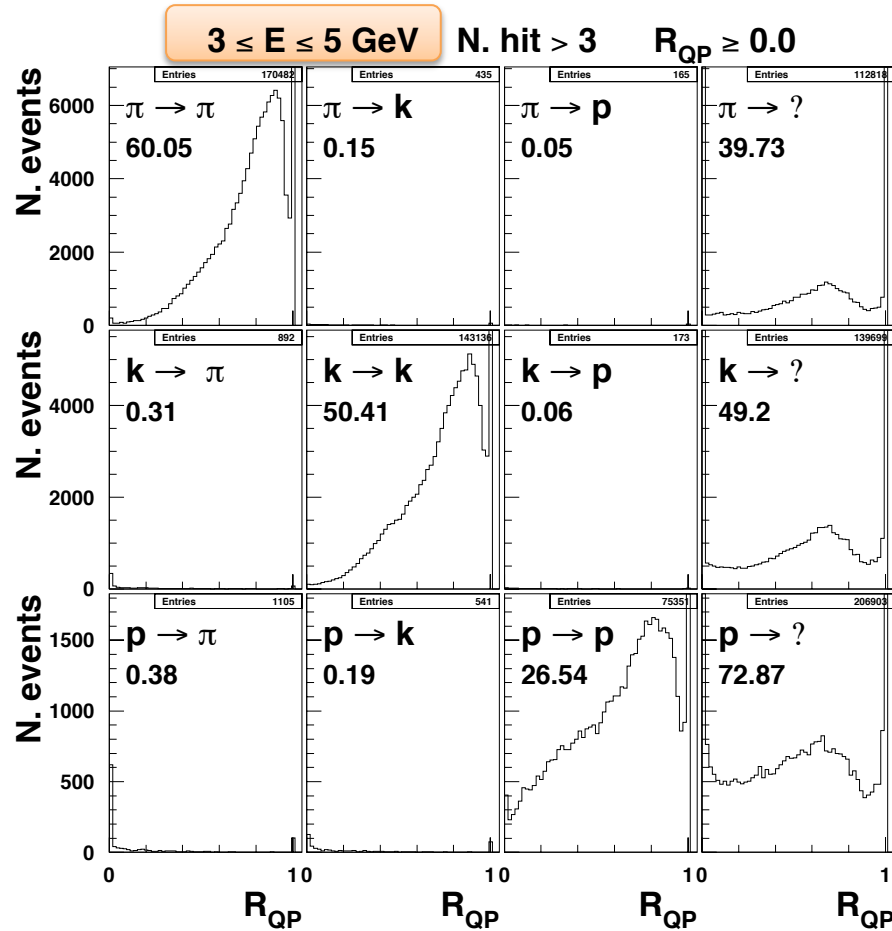

$3 \leq E \leq 8$ GeV **N. hit > 3** $R_{QP} \geq 0.0$

LH performances vs N. hits

At high momentum 3-hit event are not really useful: there best separation power is needed but RICH gets higher average number of photon hits

Hadron ID vs azimuthal angle

Almost uniform within a sector

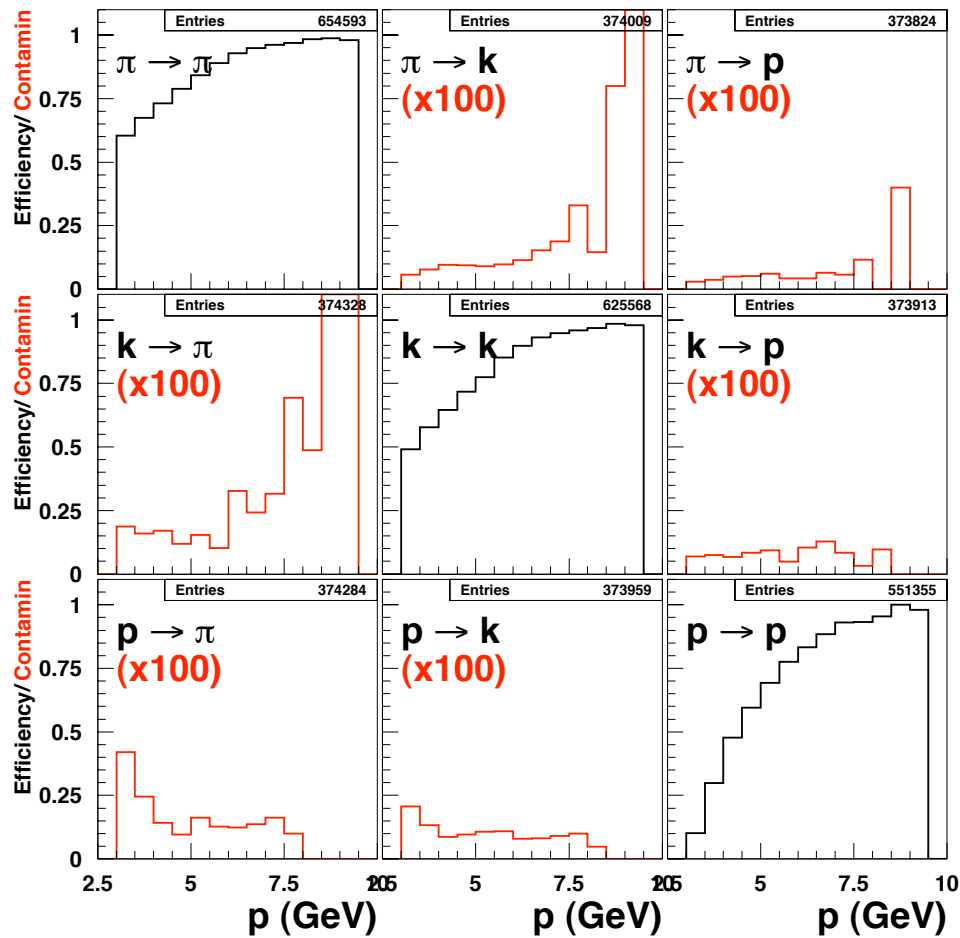

Drop in performances at the sector edge due to acceptance

Hadron ID vs momentum/polar angle

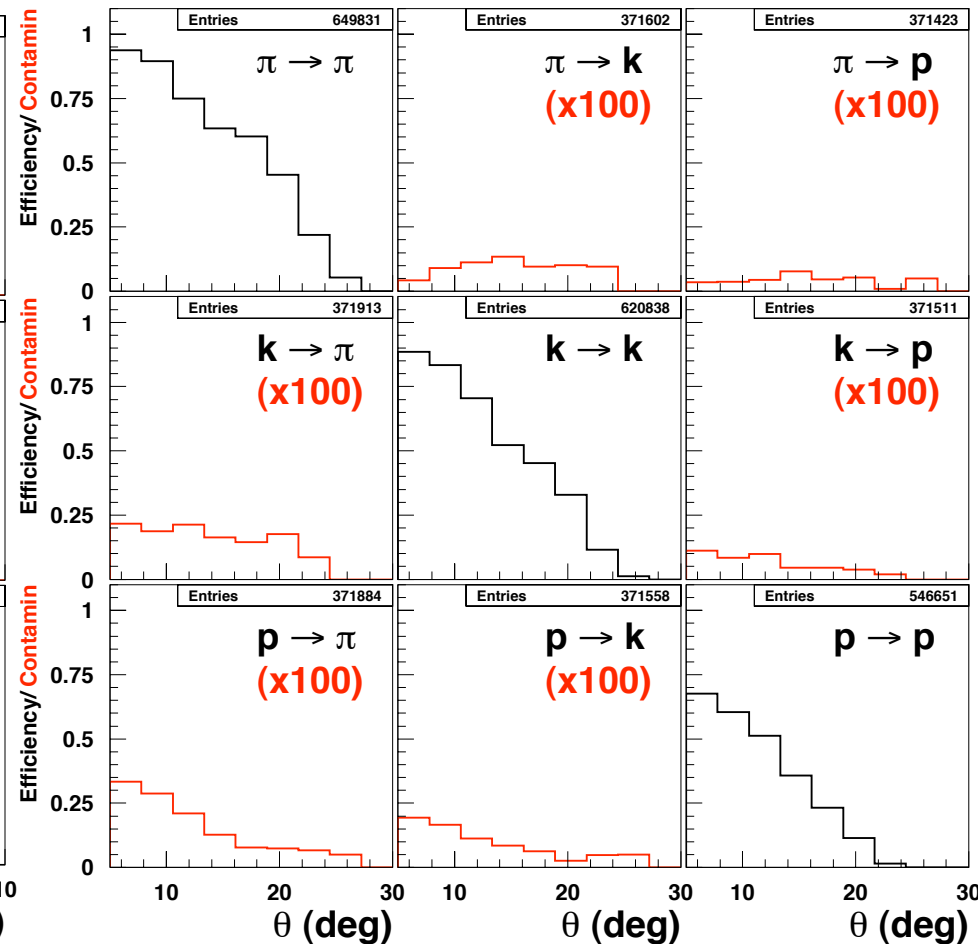

Performances vs momentum

$E > 0.0$ N. hit > 2 rQP > 0.0

Performances vs polar angle

$3 < E < 8$ GeV N. hit > 2 rQP > 0.0

Contamination diverges above 8 GeV
At small momenta correlation with polar angle

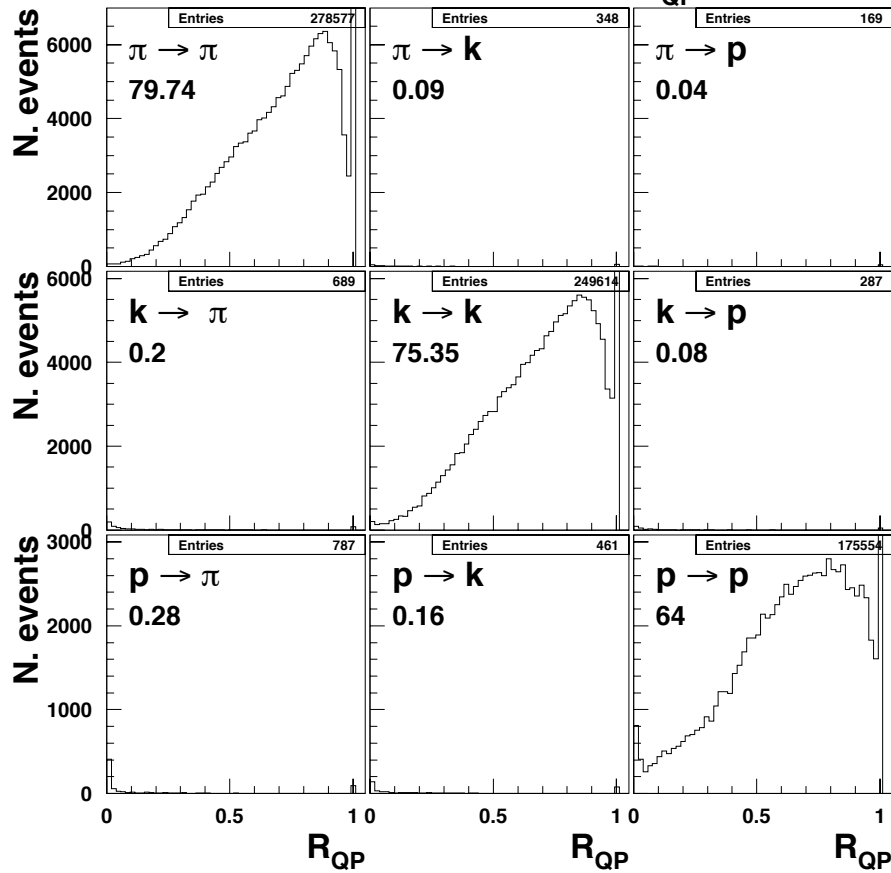

At large polar angle too few photon hits

Open vs isolated sectors

Isolated sectors show slightly worse performances

Open sector

$3 < E < 8 \text{ GeV}$ $N. \text{ hit} > 2$ $R_{QP} > 0.0$

Isolated sector

$3 < E < 8 \text{ GeV}$ $N. \text{ hit} > 2$ $R_{QP} > 0.0$

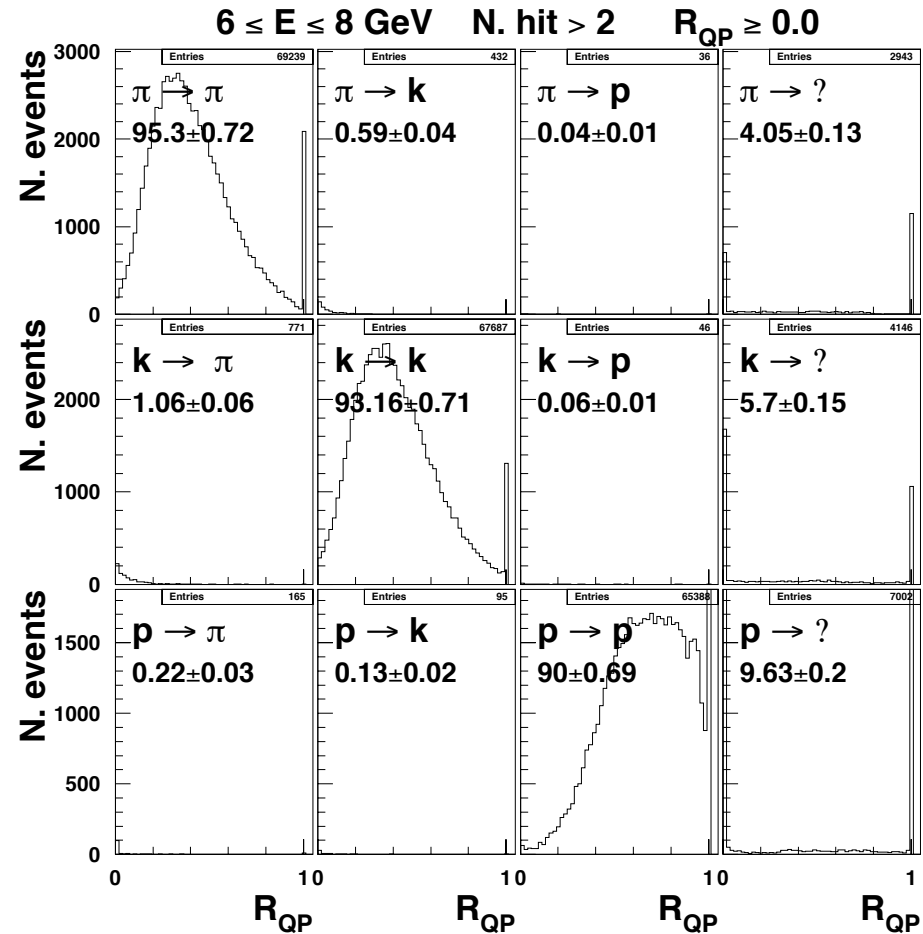

Dispersion law at $n=1.05$ (High P)

Small impact on the efficiency

Significant increase of the contamination to a still manageable level

Dispersion as 1.03

Dispersion as $n-1$

+ Rayleigh scattering (High P)

In the LH, Rayleigh scattering is treated as background
 Small worsening of the performances

Rayleigh as absorption

Rayleigh scattering

$6 \leq E \leq 8 \text{ GeV}$ $N. \text{ hit} > 2$ $R_{QP} \geq 0.0$

$6 \leq E \leq 8 \text{ GeV}$ $N. \text{ hit} > 2$ $R_{QP} \geq 0.0$

+ Rayleigh scattering (Low P)

Small worsening of the performances

Significant increase of events with too few photoelectrons: to be investigated

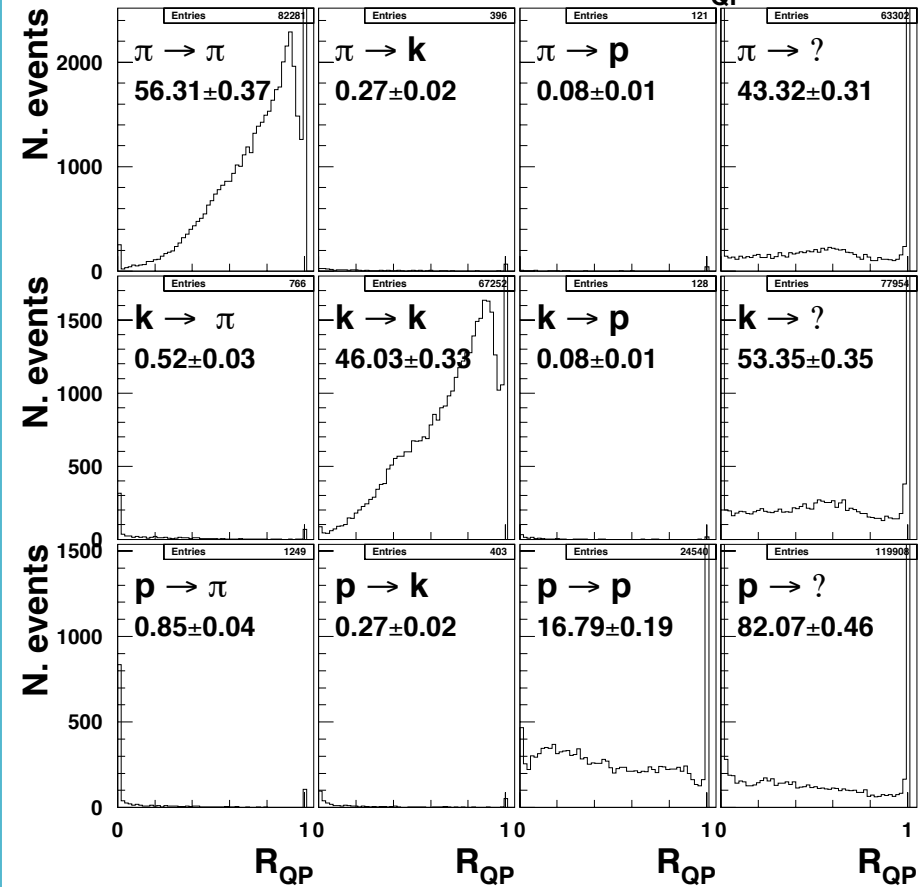

Rayleigh as absorption

Rayleigh scattering

$2.5 \leq E \leq 4 \text{ GeV}$ $N. \text{ hit} > 2$ $R_{QP} \geq 0.0$

$2.5 \leq E \leq 4 \text{ GeV}$ $N. \text{ hit} > 2$ $R_{QP} \geq 0.0$

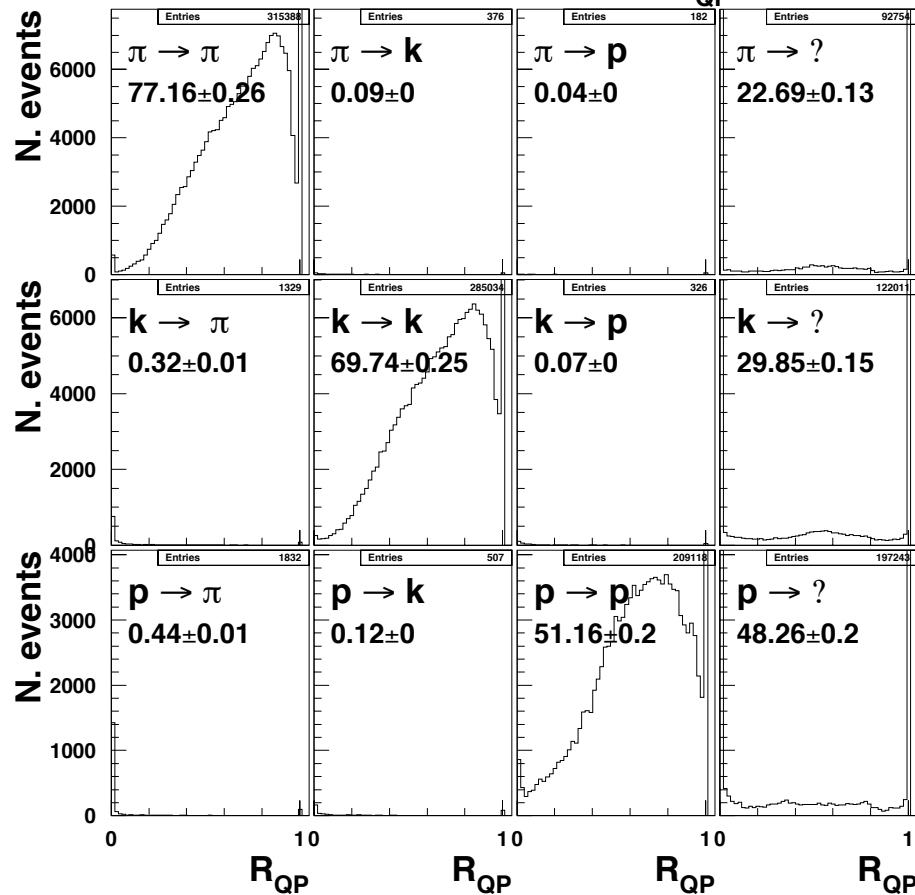

+ Rayleigh scattering

Significant increase of events with too few photoelectrons: to be investigated

Rayleigh as absorption

$3 \leq E \leq 8 \text{ GeV}$ N. hit > 2 $R_{QP} \geq 0.0$

Rayleigh scattering

$3 \leq E \leq 8 \text{ GeV}$ N. hit > 2 $R_{QP} \geq 0.0$

LH performances vs bending

Better performance for IN-bending particles
 Different R_{QP} shape

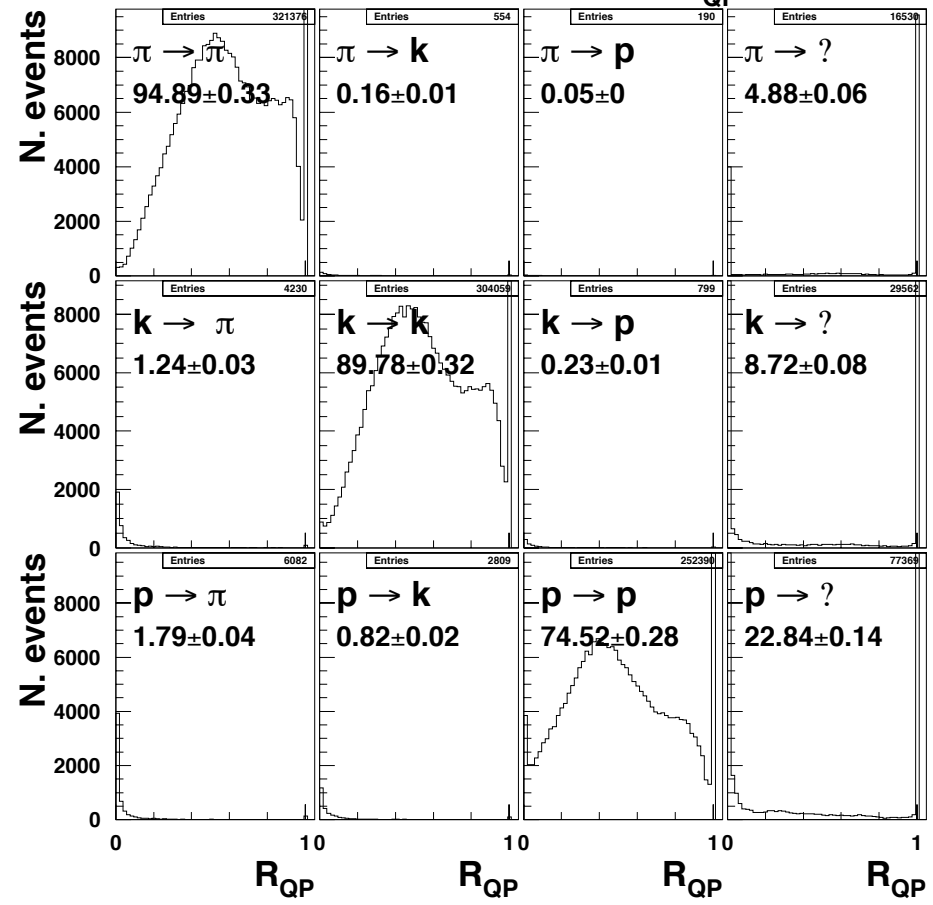

OUT-bending (positives)

$3 \leq E \leq 8 \text{ GeV}$ N. hit > 2 $R_{QP} \geq 0.0$

IN-bending (negatives)

$3 \leq E \leq 8 \text{ GeV}$ N. hit > 2 $R_{QP} \geq 0.0$

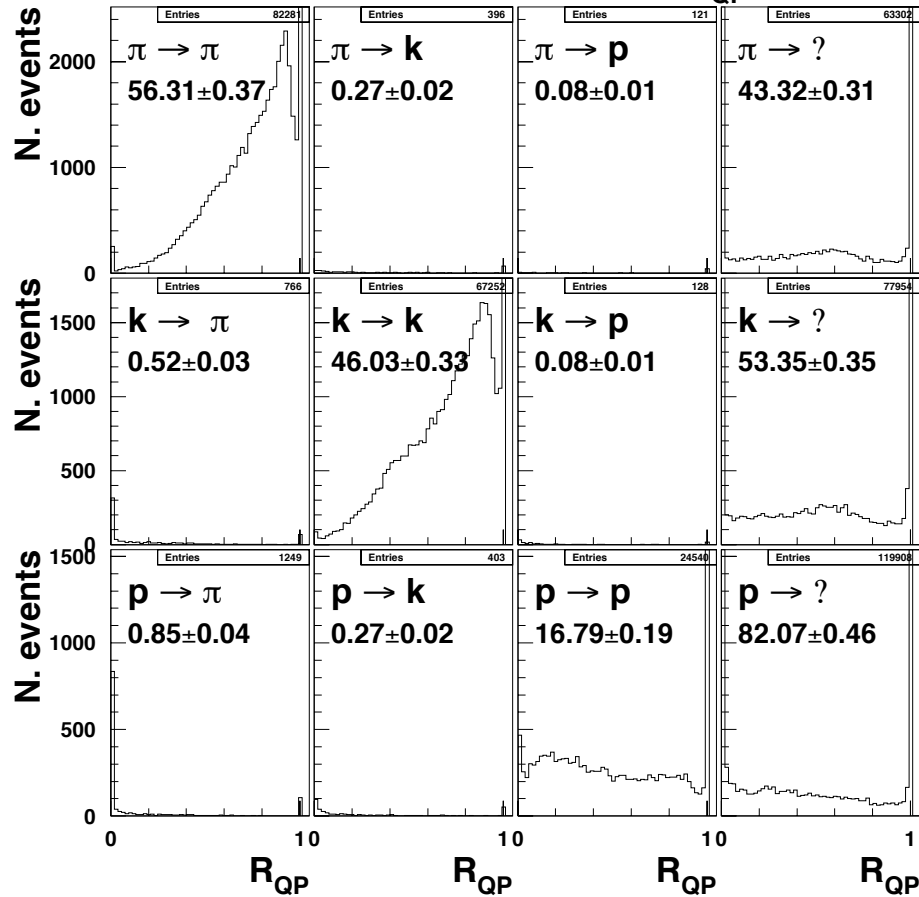

LH performances vs bending (Low P)

Different R_{QP} shape probably due to large angle, small N_{pe} events or raw fiducial volume selection

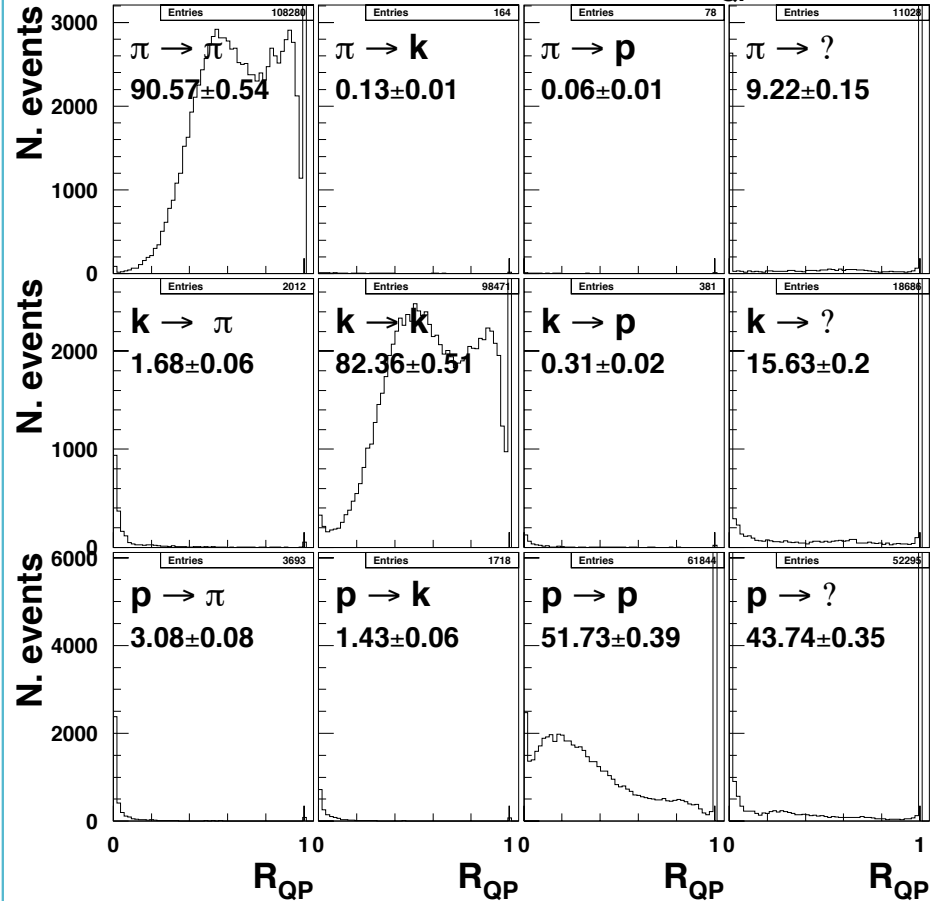

OUT-bending (positives)

$2.5 \leq E \leq 4 \text{ GeV}$ $N. \text{ hit} > 2$ $R_{QP} \geq 0.0$

IN-bending (negatives)

$2.5 \leq E \leq 4 \text{ GeV}$ $N. \text{ hit} > 2$ $R_{QP} \geq 0.0$

LH performances vs bending (High P)

Differences in R_{QP} shape vanish

OUT-bending (positives)

IN-bending (negatives)

$6 \leq E \leq 8$ GeV N. hit > 2 $R_{QP} \geq 0.0$

$6 \leq E \leq 8$ GeV N. hit > 2 $R_{QP} \geq 0.0$

LH performances vs R_{QP} cut

With R_{QP} it is possible to reduce by a factor 2 the contamination with small impact on the efficiency

OUT-bending (positives)

$3 \leq E \leq 8$ GeV N. hit > 2 $R_{QP} \geq 0.0$

OUT-bending (positives)

$3 \leq E \leq 8$ GeV N. hit > 2 $R_{QP} \geq 0.10$

LH performances vs R_{QP} cut

With R_{QP} it is possible to reduce by a factor 2 the contamination with small impact on the efficiency

IN-bending (negatives)

$3 \leq E \leq 8$ GeV N. hit > 2 $R_{QP} \geq 0.0$

IN-bending (negatives)

$3 \leq E \leq 8$ GeV N. hit > 2 $R_{QP} \geq 0.10$

LH performances in 2D

OUT-bending (positives)

$3 \leq E \leq 10$ GeV N. hit > 2 $R_{QP} \geq 0.1$

IN-bending (negatives)

$3 \leq E \leq 10$ GeV N. hit > 2 $R_{QP} \geq 0.1$

Prototype for standard set-up

Geometry:

rich_build_radtrap_mirror35_default.pl

On the Jlab GEMC database

Only one isolated sector

No magnetic field

Aerogel & PMTs as in CLAS12

9° degrees, 4 GeV/c

PMTs:
v/cr aa([nn]) R 86 77 67 56 45 35 25 15 5
sigma xx=cos(aa/[RAD])*340.+990.
sigma yy=sin(aa/[RAD])*340.

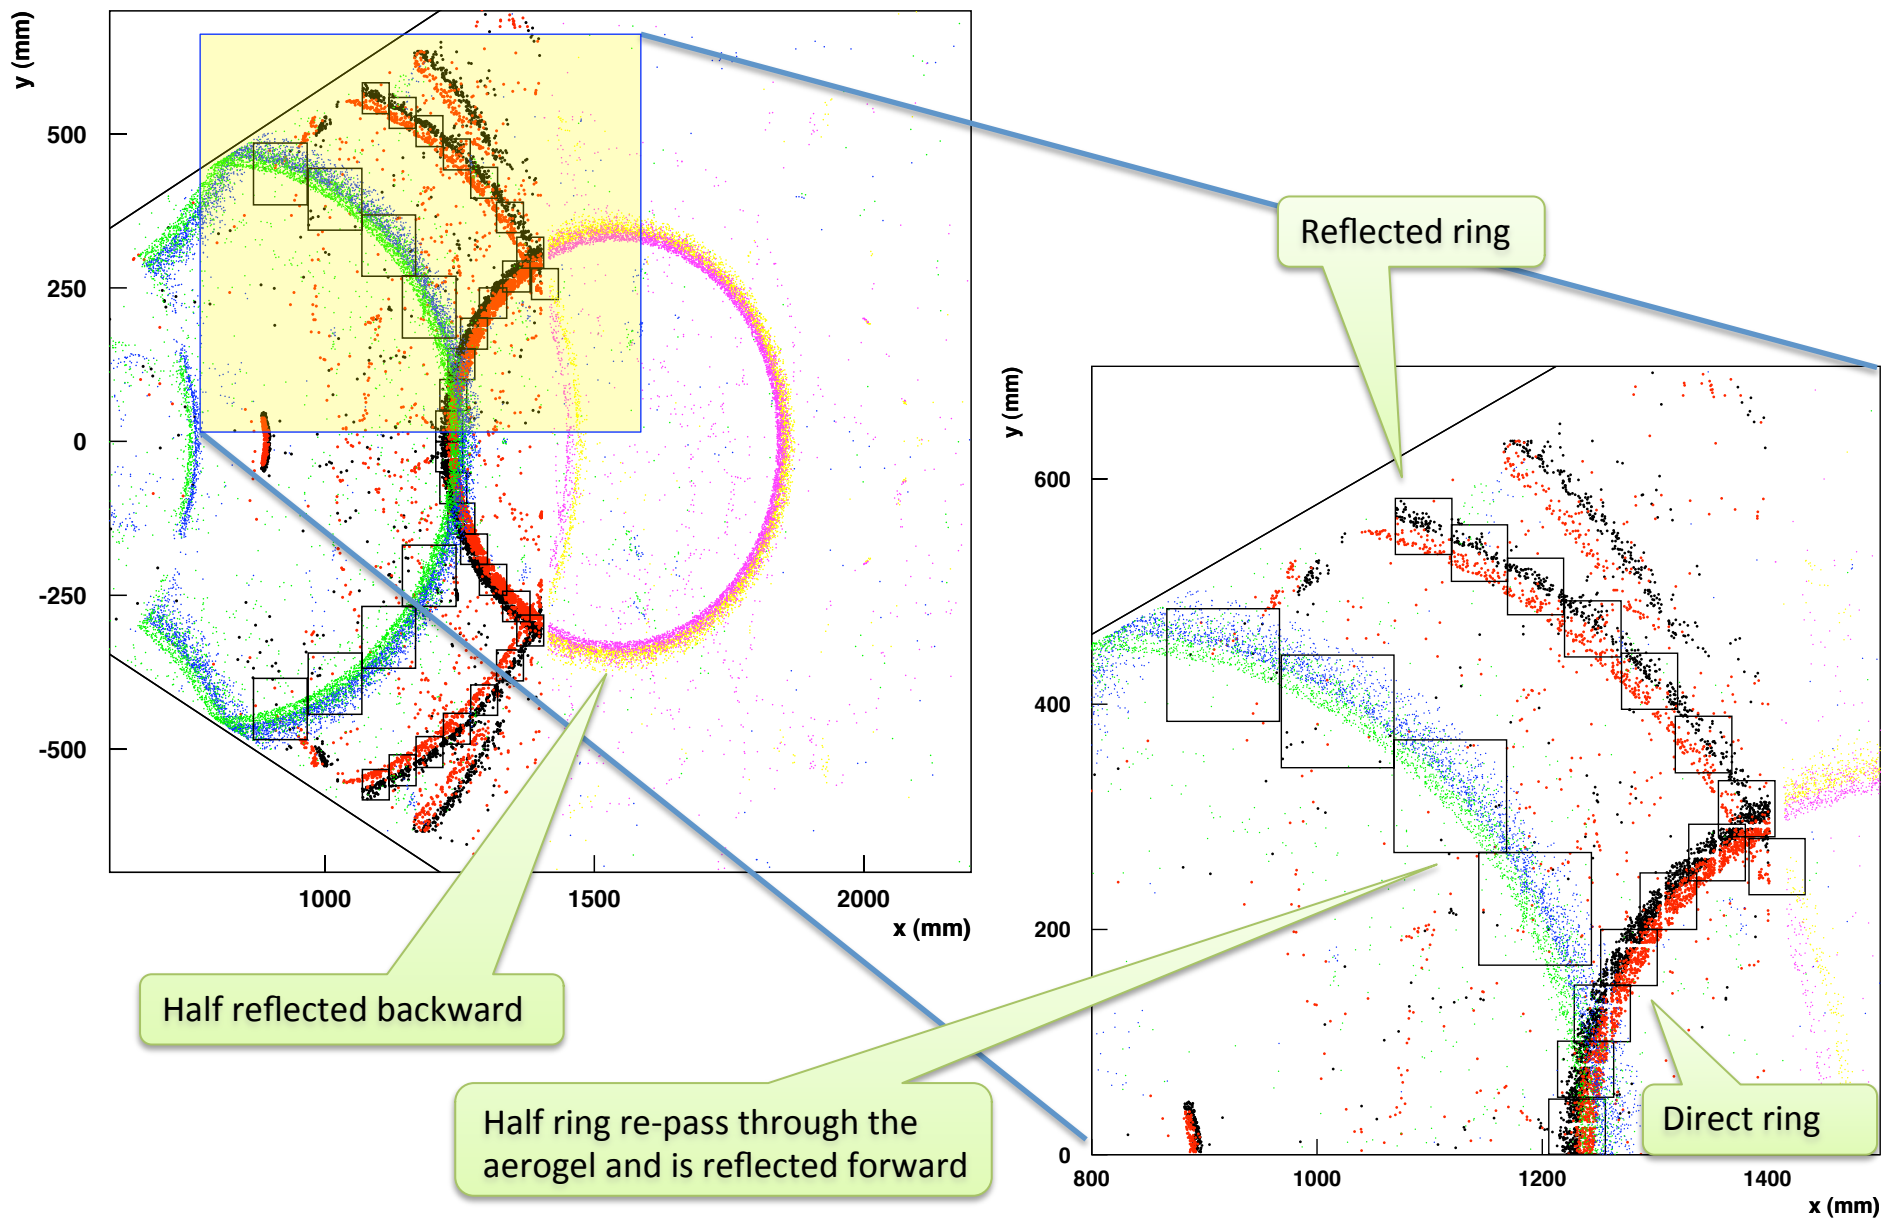

9° degrees, 8 GeV/c

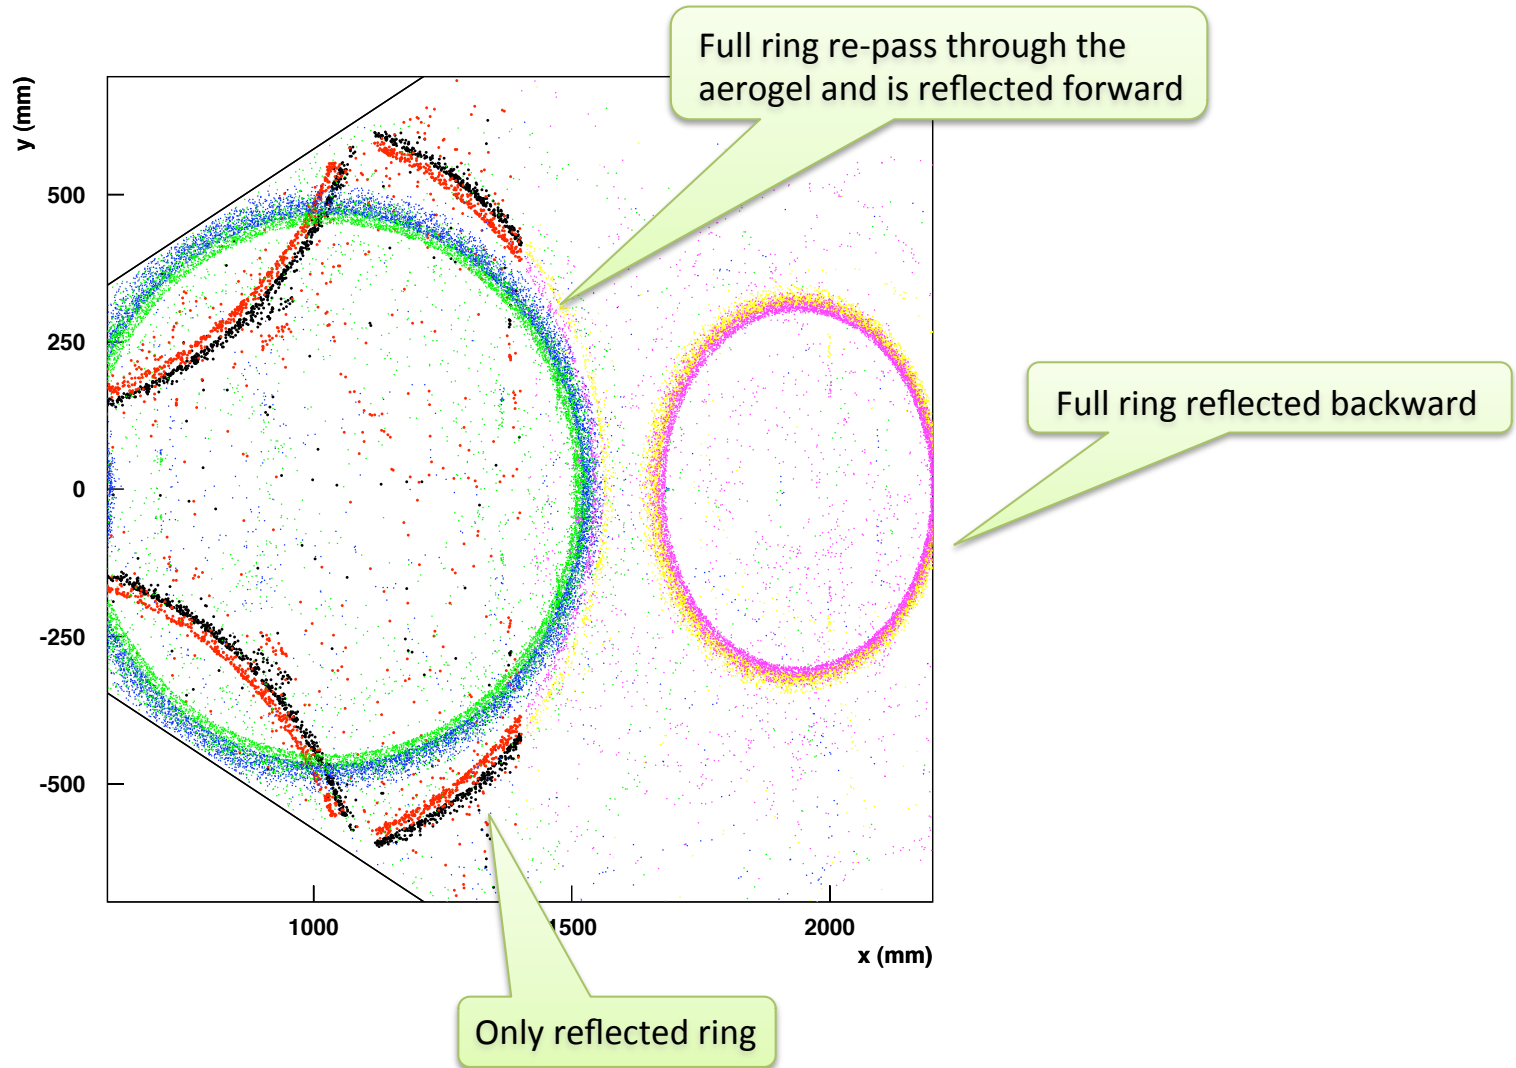

Simple configuration to test the pion-kaon separation at the upper limit in momentum

14° degrees, 6 GeV/c

18° degrees, 6 GeV/c

Conclusions

Aerogel provides in principle a good pion/kaon separation up to 8 GeV/c

- **Systematic studies performed with a GEANT3-based simulation indicate a suitable configuration for the RICH in terms of pions/kaons separation is achievable**

- **GEMC (GEANT4-based) simulation + reconstruction available**

- ✓ *Detailed geometry (**aerogel in tiles**)*
- ✓ *Optical effects (**mirror reflectivity and quality**)*
- ✓ *Digitalization*
- ✓ *Background (**Rayligh**)*
- ✓ *Realistic components characteristics*
- ✓ *Likelihood based on direct ray-tracing*
- * ***Validation of the preliminary results ongoing***
- * ***Optimal compromise to be found***

- **Proof of principle with a realistic prototype:**

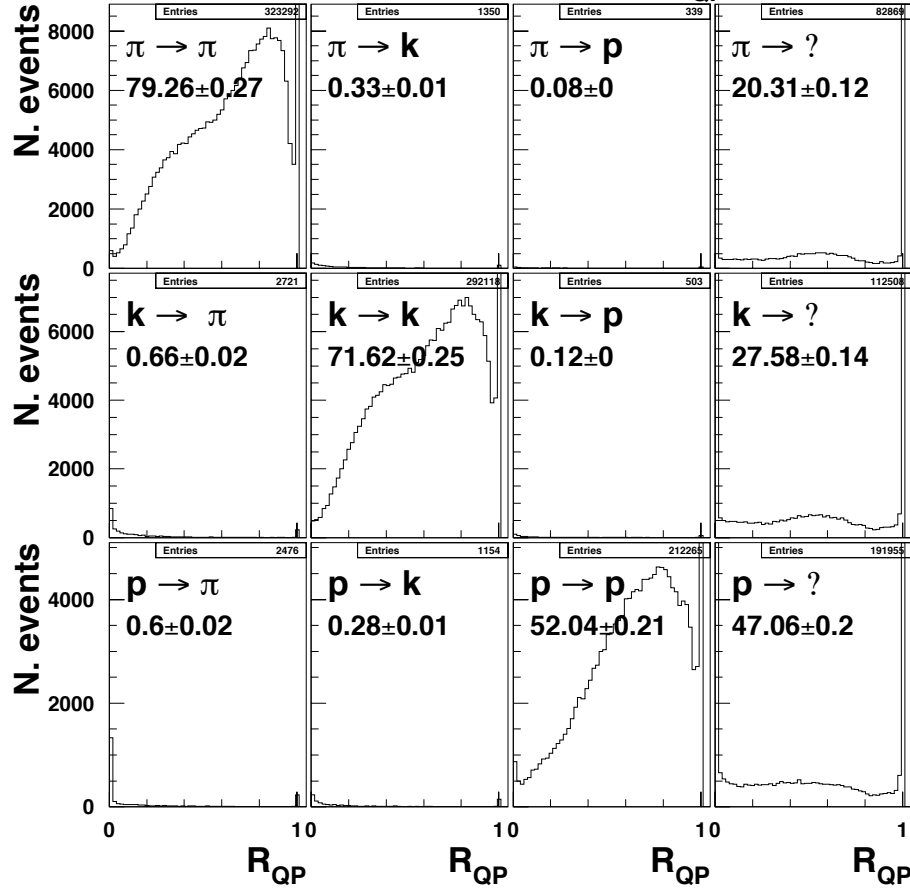

- * ***Performances at upper momentum limit (up to 8 GeV/c)***
- * ***Double reflection concept***
- * ***Hardware components***

TEST

In the LH, Rayleigh scattering is treated as background
 Significant increase of events with too few photoelectrons: to be investigated

Iside rayleigh

$3 \leq E \leq 8 \text{ GeV}$ N. hit > 2 $R_{QP} \geq 0.0$

Anubis rayleigh

$3 \leq E \leq 8 \text{ GeV}$ N. hit > 2 $R_{QP} \geq 0.0$
