

# Cmake

CMake is a build configuration tool

- it takes a configuration file (CMakeLists.txt)
- it finds all dependencies (in our case, Geant4)
- creates a Makefile to run the compilation itself

You have to write this CMakeLists.txt file

- take inspiration from examples
- be sure to set the name of your application correctly
- specify all auxiliary files you need

Note: It is possible but discouraged to base build on GNU make instead of CMake.
