

## PART III

# Magnetic Field

---

- *Field Propagation & accuracy*
- *Global & Local Field*
- *Tunable parameters*
- *Field Integration*

# Field Propagation

---

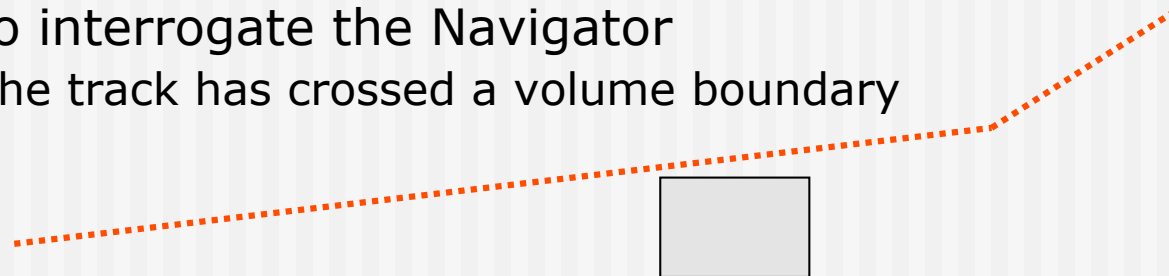

- In order to propagate a particle inside a field (e.g. magnetic, electric or both), we integrate the equation of motion of the particle in the field
- In general this is best done using a **Runge-Kutta** (RK) method for the integration of ordinary differential equations
  - Several RK methods are available
- In specific cases other solvers can also be used:
  - In a uniform field, using the known analytical solution
  - In a nearly uniform but varying field, with RK+Helix

# Chords

- Once a method is chosen that allows Geant4 to calculate the track's motion in a field, Geant4 breaks up this curved path into linear chord segments

- The chord segments are determined so that they closely approximate the curved path; they're chosen so that their **sagitta** is small enough
  - The *sagitta* is the maximum distance between the curved path and the straight line
  - Small enough: is smaller than a user-defined maximum
- Chords are used to interrogate the Navigator
  - to see whether the track has crossed a volume boundary

# Intersection accuracy

- The accuracy of the volume intersection can be tuned
  - by setting a parameter called the “miss distance”
    - The *miss distance* is a measure of the error resolution by which the chord may intersect a volume
    - Default *miss distance* is 0.25 mm
    - Setting small *miss distance* may be highly CPU consuming
- One step can consist of more than one chord
  - In some cases, one step consists of several turns

# How to set a Magnetic Field ...

---

- Magnetic field class
  - Uniform field :  
G4UniformMagField class object
  - Non-uniform field :  
Concrete class derived from G4MagneticField
- Set it to G4FieldManager and create a Chord Finder

```
G4FieldManager* fieldMgr =  
    G4TransportationManager::GetTransportationManager()  
        ->GetFieldManager();  
fieldMgr->SetDetectorField(magField);  
fieldMgr->CreateChordFinder(magField);
```

# Global & Local Fields

- One field manager is associated with the 'world'
- Other volumes/regions in the geometry can override this
  - An alternative field manager can be associated with any logical volume
    - The field must accept **position in global coordinates** and return **field in global coordinates**
  - The assigned field is propagated to all the daughter volumes

```
G4FieldManager* localFieldMgr = new G4FieldManager(magField);
logVolume->setFieldManager(localFieldMgr, true);
```

where 'true' makes it *push* the field to all the daughter volumes, unless a daughter has its own field manager.
- It is possible to customise the field propagation classes
  - Choosing an appropriate stepper for the field
  - Setting precision parameters

# Tunable Parameters

- In addition to the “miss distance” there are two more parameters which can be set in order to adjust the accuracy (and performance) of tracking in a field
  - Such parameters govern the accuracy of the intersection with a volume boundary and the accuracy of the integration of other steps
- The “delta intersection” parameter is the accuracy to which an intersection with a volume boundary is calculated.
  - This parameter is especially important because it is used to limit a bias that the algorithm (for boundary crossing in a field) exhibits
  - The intersection point is always on the 'inside' of the curve. By setting a value for this parameter that is much smaller than some acceptable error, one can limit the effect of this bias

# Tunable Parameters

---

- The “delta one step” parameter is the accuracy for the endpoint of 'ordinary' integration steps, those which do not intersect a volume boundary
  - It is a limit on the estimation error of the endpoint of each physics step
- Parameters “delta intersection” and “delta one step” are strongly coupled
  - These values must be reasonably close to each other (within one order of magnitude)
- Parameters can be set by:

```
theChordFinder->SetDeltaChord ( miss_distance );  
theFieldManager->SetDeltaIntersection ( delta_intersection );  
theFieldManager->SetDeltaOneStep ( delta_one_step );
```

# Imprecisions ...

---

- ... are due to approximating the curved path by linear sections (chords)
  - Parameter to limit this is maximum sagitta  $\delta_{\text{chord}}$
- ... are due to numerical integration, 'error' in final position and momentum
  - Parameters to limit are  $\epsilon_{\text{integration}}$  max, min
- ... are due to intersecting approximate path with the volume boundary
  - Parameter is  $\delta_{\text{intersection}}$

# Key elements

- Precision of track required by the user relates primarily to:
  - The precision (error in position)  $e_{pos}$  after a particle has undertaken track length  $s$
  - Precision DE in final energy (momentum)  $\delta_E = \Delta E / E$
  - Expected maximum number  $N_{int}$  of integration steps
- Recipe for parameters:
  - Set  $\epsilon_{integration} (min, max)$  smaller than
    - The minimum ratio of  $e_{pos} / s$  along particle's trajectory
    - $\delta_E / N_{int}$  the relative error per integration step (in E/p)
  - Choosing how to set  $\delta_{chord}$  is less well-defined. One possible choice is driven by the typical size of the geometry (size of smallest volume)

# Where to find the parameters ...

Parameter	Name	Class	Default value
$\delta_{\text{miss}}$	DeltaChord	G4ChordFinder	0.25 mm
$d_{\text{min}}$	stepMinimum	G4ChordFinder	0.01 mm
$\delta_{\text{intersection}}$	DeltaIntersection	G4FieldManager	1 micron
$\epsilon_{\text{max}}$	epsilonMax	G4FieldManager	0.001
$\epsilon_{\text{min}}$	epsilonMin	G4FieldManager	5 $10^{-5}$
$\delta_{\text{one step}}$	DeltaOneStep	G4FieldManager	0.01 mm

# Volume miss error

- Due to the approximation of the curved path by linear sections (chords)

- Parameter  $\delta_{\text{chord}}$  = maximum sagitta

- Effect of this parameter as  $\delta_{\text{chord}} \rightarrow 0$

$$S_{1\text{step}}^{\text{propagator}} \sim (8 \delta_{\text{chord}} R_{\text{curv}})^{1/2}$$

so long as  $s^{\text{propagator}} \leftarrow s^{\text{phys}}$  and  $s^{\text{propagator}} > d_{\text{min}}(\text{integr})$

# Integration error

Due to error in the numerical integration (of equations of motion)

Parameter(s):  $\epsilon_{\text{integration}}$

- The size  $s$  of the step is limited so that the estimated errors of the final position  $\Delta r$  and momentum  $\Delta p$  are both small enough:

$$\max( || \Delta r || / s , || \Delta p || / || p || ) < \epsilon_{\text{integration}}$$

- For Classical RK4 Stepper

$$s_{\text{1step}}^{\text{integration}} \sim (\epsilon_{\text{integration}})^{1/3}$$

for small enough  $\epsilon_{\text{integration}}$

- The integration error should be influenced by the precision of the knowledge of the field (measurement or modeling ).

$$N_{\text{steps}} \sim (\epsilon_{\text{integration}})^{-1/3}$$

Detector Description: Sensitive Detector & Field - Geant4 Course

# Integration error - 2

- $\epsilon_{\text{integration}}$  is currently represented by 3 parameters

- **epsilonMin**, a minimum value (used for big steps)
- **epsilonMax**, a maximum value (used for small steps)
- **DeltaOneStep**, a distance error (for intermediate steps)

*Defaults*

*$0.5 \cdot 10^{-7}$*

*0.05*

*0.25 mm*

$$\epsilon_{\text{integration}} = \delta_{\text{one step}} / S_{\text{physics}}$$

- Determining a reasonable value

- Suggested to be the minimum of the ratio (accuracy/distance) between sensitive components, ...

- Another parameter

- $d_{\text{min}}$  is the minimum step of integration

*Default*

*0.01 mm*

# Intersection error

- In intersecting approximate path with volume boundary
  - In trial step AB, intersection is found with a volume at C
  - Step is broken up, choosing D, so
$$S_{AD} = S_{AB} * |AC| / |AB|$$
  - If  $|CD| < \delta_{\text{intersection}}$ 
    - Then C is accepted as intersection point.
  - So  $\delta_{\text{int}}$  is a position error/bias

# Intersection error - 2

- $\delta_{\text{int}}$  must be small
  - compared to tracker hit error
  - its effect on reconstructed momentum estimates should be calculated
    - ... and limited to be acceptable
- Cost of small  $\delta_{\text{int}}$  is less
  - than making  $\delta_{\text{chord}}$  small
  - it is proportional to the number of boundary crossings – not steps
- Quicker convergence / lower cost
  - Possible with optimization

# Customizing field integration

- **Runge-Kutta** integration is used to compute the motion of a charged track in a general field. There are many general steppers from which to choose
  - Low and high order, and specialized steppers for pure magnetic fields
- By default, Geant4 uses the classical fourth-order **Runge-Kutta** stepper (**G4ClassicalRK4**), which is general purpose and robust.
  - If the field is known to have specific properties, lower or higher order steppers can be used to obtain the results of same quality using fewer computing cycles
- If the field is calculated from a field map, a lower order stepper is recommended
  - The less smooth the field is, the lower the order of the stepper that should be used
  - The choice of lower order steppers includes the third order stepper (**G4SimpleHeum**) the second order (**G4ImplicitEuler** and **G4SimpleRunge**), and the first order (**G4ExplicitEuler**)
    - A first order stepper would be useful only for very rough fields
    - For somewhat smooth fields (intermediate), the choice between second and third order steppers should be made by trial and error

# Customizing field integration

---

- Trying a few different types of steppers for a particular field or application is suggested if maximum performance is a goal
- Specialized steppers for pure magnetic fields are also available
  - They take into account the fact that a local trajectory in a slowly varying field will not vary significantly from a helix
  - Combining this in with a variation, the Runge-Kutta method can provide higher accuracy at lower computational cost when large steps are possible

- To change the stepper:

**theChordFinder**

**->GetIntegrationDriver()**

**->RenewStepperAndAdjust( newStepper );**

# Other types of field

- It is possible to create any specialised type of field:
  - inheriting from `G4VField`
  - Associating an *Equation of Motion* class (inheriting from `G4EqRhs`) to simulate other types of fields
  - Fields can be time-dependent
- For pure electric field:
  - `G4ElectricField` and `G4UniformElectricField` classes
- For combined electromagnetic field:
  - `G4ElectroMagneticField` class
- The *Equation of Motion* class for electromagnetic field is `G4MagElectricField`.

```
G4ElectricField* fEMfield
    = new G4UniformElectricField( G4ThreeVector(0., 100000.*kilovolt/cm, 0.) );
G4EqMagElectricField* fEquation = new G4EqMagElectricField(fEMfield);
G4MagIntegratorStepper* fStepper = new G4ClassicalRK4( fEquation, nvar );
G4FieldManager* fFieldMgr
    = G4TransportationManager::GetTransportationManager()->GetFieldManager();
fFieldMgr->SetDetectorField( fEMfield );
G4MagInt_Driver* fIntgrDriver
    = new G4MagInt_Driver(fMinStep, fStepper, fStepper->GetNumberOfVariables() );
G4ChordFinder* fChordFinder = new G4ChordFinder(fIntgrDriver);
```
